SIX DEGREES OF FREEDOM VIBRATION ISOLATION USING ELECTROMAGNETIC SUSPENSION

Sang-il Lee¹, Daniel B. DeBra², Peter F. Michelson³,
Robert C. Taber⁴, John C. Price⁴

ABSTRACT

Experimental data are presented for modelling an electromagnet. Control laws are considered with and without flux feedback and with position and orientation information of the suspended body. Base motion and sensor noise are the principal disturbances. Proper selection of the geometrical operating point minimizes the passive coupling above the bandwidth of the control and filtering can attenuate the high frequency content of sensor noise. Six electromagnets are arranged in a configuration which optimizes the load support and provides control over all six degrees of freedom of the suspended body. The design is based on experimental data generated with a specially designed test facility. Application for suspension of a gravity wave antenna is discussed.

INTRODUCTION

Isolation from base motion is frequently required. On the ground, precise instruments must be isolated from the cultural and natural seismic motion of the earth. In orbit, the motion of a spacecraft may be significant due to moving machinery, thrusters or the presence of man [1,2]. Many techniques are available. Mechanical devices such as coil springs, air cushions or compliant materials offer the advantage of simplicity and reliability. By using stacks of such devices, rapid attenuation with frequency can be achieved. But the mechanical link remains and when internal resonances, cross coupling of degrees of freedom and nonlinearity exist, the idealized attenuation hoped for is not always achieved. Passive or active feedback techniques using magnetic or electrostatic fields can remove the mechanical link and permit an improved degree of isolation. Examples include the electrostatic gyro [3] which can achieve spin down time constant of hundreds of years, passively suspended superconducting proof masses for a principle of equivalence experiment [4] and an eddy current suspension for gradiometers [5] and many forms of active and passive magnetic suspension reviewed by Jayawant [6]. An interesting variant is to shield a proof mass on orbit and use it as a reference thus producing a drag free satellite [7], which has achieved average disturbances of less than $5 \times 10^{-12}g$.

For an active isolation system, the suspended body follows its reference within the bandwidth of the feedback control. Thus isolation only occurs for frequencies above the bandwidth (natural frequency) of the control. Though the mechanical link is gone, displacement dependence of the force may remain and produces coupling which cannot be influenced by the feedback. Thus one desires to design an actuator which has no spatial dependence on force or has a local extremum so that the small-motion dependence is small. We will give an example later. The force used for suspension is generated as a function of measurements. These measurements are noisy and produce a component of force which is a disturbance. But the frequency content of this disturbance is under the control of the designer by appropriate filtering.

Certainly the most exquisitely sensitive instruments ever developed are the gravity wave antennas. Current bar antennas are capable of detecting strains of 10^{-18} and it is hoped bars can reach 10^{-20} .
