

Unit 6: Evolution

Population Genetics (Chapter 11)

I. Genes and Variation

- The two main sources of genetic variation are mutations and the genetic shuffling that results from sexual reproduction. (gene shuffling brings together new combinations of genes)
- allelic frequency –the percentage of a particular allele (trait) in a gene pool.
- camouflage –organisms blend in with surrounding environment
- mimicry –species copy another to insure their own survival
- gene pool –all the genes that exist within a population
- single-gene trait – can produce only two phenotypes (ie, attached or unattached earlobes)
- polygenic trait – can produce many phenotypes (produce a bell curve)
- gene flow –movement of alleles into or out of a population
- genetic drift –change in allelic frequencies by chance

Ex: sudden extinction of a dominant species; small populations most affected

- genetic equilibrium –when alleles remain constant (stay the same) from generation to generation

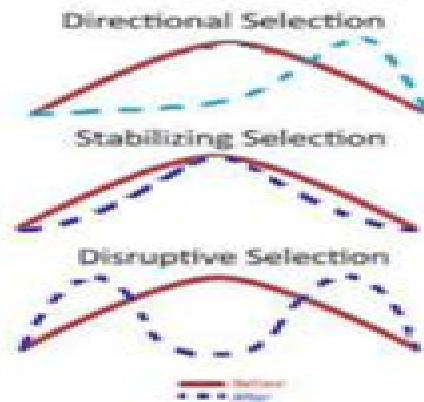

II. Evolution as Genetic Change

Natural selection works on the individual level, but affects the population.

Natural selection on single-gene traits can lead to changes in allele frequencies and thus to evolution.

Natural selection on polygenic traits can affect the distribution of phenotypes in any of three ways:

- Direct Selection-Individuals on one end of a curve are “better fitted” than the middle or other end
- Stabilizing Selection- Individuals near center of a curve are “better fitted” than both ends
- Disruptive Selection- Individuals at upper and lower ends are “better fitted” the ones in the middle
