

# The Statistical Analysis of fMRI Data

Martin A. Lindquist

**Abstract.** In recent years there has been explosive growth in the number of neuroimaging studies performed using functional Magnetic Resonance Imaging (fMRI). The field that has grown around the acquisition and analysis of fMRI data is intrinsically interdisciplinary in nature and involves contributions from researchers in neuroscience, psychology, physics and statistics, among others. A standard fMRI study gives rise to massive amounts of noisy data with a complicated spatio-temporal correlation structure. Statistics plays a crucial role in understanding the nature of the data and obtaining relevant results that can be used and interpreted by neuroscientists. In this paper we discuss the analysis of fMRI data, from the initial acquisition of the raw data to its use in locating brain activity, making inference about brain connectivity and predictions about psychological or disease states. Along the way, we illustrate interesting and important issues where statistics already plays a crucial role. We also seek to illustrate areas where statistics has perhaps been underutilized and will have an increased role in the future.

## 1. INTRODUCTION

Functional neuroimaging has experienced an explosive growth in recent years. Currently there exist a number of different imaging modalities that allow researchers to study the physiological changes that accompany brain activation. Each of these techniques has advantages and disadvantages and each provides a unique perspective on brain function. In general, these techniques are not concerned with the behavior of single neurons, but rather with activity arising from a large group of neurons. However, they differ in what they attempt to measure, as well as in the temporal and spatial resolution that they provide. Techniques such as electroencephalography (EEG) and magnetoencephalography (MEG) are based on studying electrical and magnetic activity in the brain. They provide temporal resolution on the order of milliseconds but uncertain spatial localization. In contrast, functional magnetic resonance imaging (fMRI) and positron emission tomography (PET) provide information on blood flow

changes that accompany neuronal activity with relatively high spatial resolution, but with a temporal resolution limited by the much slower rate of brain hemodynamics. While each modality is interesting in its own right, this article focuses on statistical issues related to fMRI which in the past few years has taken a dominant position in the field of neuroimaging.

Functional MRI is a noninvasive technique for studying brain activity. During the course of an fMRI experiment, a series of brain images are acquired while the subject performs a set of tasks. Changes in the measured signal between individual images are used to make inferences regarding task-related activations in the brain. fMRI has provided researchers with unprecedented access to the brain in action and, in the past decade, has provided countless new insights into the inner workings of the human brain.

There are several common objectives in the analysis of fMRI data. These include localizing regions of the brain activated by a task, determining distributed networks that correspond to brain function and making predictions about psychological or disease states. Each of these objectives can be approached through the application of suitable statistical methods, and statisticians play an important role in the interdisciplinary

**Patterns** Alena Mysickova, 2017 Decision making usually involves uncertainty and risk. Understanding which parts of the human brain are activated during decisions under risk and which neural processes underly risky investment decisions are important goals in neuroeconomics. Here we reanalyze functional magnetic resonance imaging fMRI data on 17 subjects which were exposed to an investment decision task from Mohr et al 2010b. We obtain a time series of three dimensional images of the blood oxygen level dependent BOLD fMRI signals. Our goal is to capture the dynamic behavior of specific brain regions of all subjects in this high dimensional time series data by a flexible factor approach resulting in a low dimensional representation. We apply a panel version of the dynamic semiparametric factor model DSFM presented in Park et al 2009 and identify task related activations in space and dynamics in time. Further we classify the risk attitudes of all subjects based on the estimated lowdimensional time series. Our classification analysis successfully confirms the estimated risk attitudes derived directly from subjects decision behavior.

Second we compare differences of groups of subjects in brain activation changes across two scan sessions Using the property that brain signals in regions of interest ROIs may contain a similar pattern across subjects in a task related experiment we develop a semiparametric approach under shape invariance to quantify and test differences between sessions and groups We conduct statistical inference on the scale parameter in the model to determine whether attenuation is present between two sessions for each group and whether a group difference exists between two sessions in multiple ROIs Last we take a functional data analysis approach to classify fMRI data We propose a spatially weighted functional support vector machine FSVM that utilizes a parameter to estimate correlation between different brain regions Using both numerical study and a real fMRI dataset we show our proposed method achieves higher classification accuracy compared to a regular FSVM method     *Use of Statistical Classifiers in the Analysis of FMRI Data* Thomas William John Ash,2011     **The Development of Biomarkers in Psychiatry** Takashi Nakano,Takahiro A.
