

Hybrid-variant recognition is a process of identifying and classifying variants in a sample based on their sequence profile. This process involves several steps, including initial screening of the sample for specific variants, followed by sequencing and analysis of the variants to determine their characteristics and potential clinical significance. The final output of this process is a report that includes a detailed description of the variants found in the sample, along with their estimated frequency and any associated clinical information.

- **Initial screening:** This step involves identifying the presence of specific variants in the sample. This can be done using various methods, such as sequencing, PCR, or mass spectrometry. The results of this step are used to guide the subsequent analysis of the variants.
- **Sequencing:** This step involves sequencing the variants found in the sample. This can be done using various methods, such as Sanger sequencing, next-generation sequencing, or capillary sequencing. The results of this step are used to determine the sequence profile of each variant.
- **Analysis:** This step involves analyzing the sequence profile of each variant. This can be done using various methods, such as bioinformatics tools, machine learning algorithms, or expert knowledge. The results of this step are used to determine the characteristics of each variant, such as its frequency, clinical significance, and potential impact on the sample.

Variant Type	Sequence	Frequency
Variant A	ATGCGT	0.15
